(54) DISC SYSTEM

(57) A disc device which protects the disc therein from damage. An upper disc roller (201) and a lower disc roller (202) are provided in the disc insertion opening of a housing (100), and a roller open cam plate (203) for adjusting the gaps (d2, d3, d4) between the upper disc roller (201) and the lower disc roller (202) is provided.

FIG.1

EP 0 915 463 A1

Description

Technical Field

[0001] The present invention relates to a disk system, and particularly to a disk system capable of preventing a disk from being damaged by holding the disk upon insertion or ejection of the disk and moving both roller portions holding the disk upon reproducing or exchange of the disk.

Background Art

[0002] Fig. 106 is a sectional side view showing an essential portion of a related art general disk system capable of selectively operating a plurality of disks, and Fig. 107 is a sectional view of the essential portion.

[0003] In Figs. 106 and 107, reference numeral 1 indicates a magazine in which exchange disks are contained, and 2 is a disk rotating portion. The disk rotating portion 2 includes a disk rotating motor 3; a disk clamp hub 13 provided on a shaft of the disk rotating motor 3; a disk clasper 4; a disk roller 6 for feeding, a disk 8 which is fed out by a driving lever 5 provided in the magazine 1 and driven by a driving means (not shown), to the disk rotating portion 2; a driving shaft 9 fixed on a housing 7 for supporting the disk rotating portion 2; and a tilting plate cam 10 and upper and lower guide plates 11 operated in the direction A in the figures.

[0004] In this disk system, to take off a plurality of the disks 8 contained in the magazine 1, the disk rotating portion 2 is moved in the direction B in the figures by interlocking of the driving shaft 9, tilting plate cam 10 and upper and lower guide plates 11, to be positioned at a desired disk position in the magazine 1.

[0005] In this way, according to the related art disk system, since disks contained in the magazine 1 are perfectly independent from a disk rotated on the disk rotating portion 2 side within a plane region, there occurs a problem that a length, that is, a dimension D of the disk system becomes larger.

[0006] To solve the above problem, for example, Japanese Patent Laid-open No. Sho 63-200354 has proposed a disk system. Fig. 108 is a sectional side view of an essential portion of such a disk system, and Fig. 109 is a sectional top view of the essential portion of the disk system.

[0007] In Figs. 108 and 109, reference numeral 19 indicates a magazine for containing exchange disks; 21 is a disk rotating motor; 22 is a disk clamp hub provided on a shaft of the disk rotating motor 21; and 23 is a disk clasper.

[0008] Reference numeral 26 indicates a disk roller for feeding a disk 25 fed by a driving lever 24 driven by a driving means (not shown) to a disk rotating portion, and 27 is a driven roller disposed opposite to the disk roller 26.

[0009] Reference numeral 32 indicates a pair of tilting

plate cams which are engaged with a plurality of trays 31 in the magazine 19. When the disk 25 selected by a magazine moving means (not shown) is moved in the direction of the plane of the disk, the pair of tilting plate cams 32 provide a space E more than at least a plate thickness of the disk in the rotating axis of the disk 25 with respect to the disk rotating portion 20.

[0010] Here, the disk rotating portion 20 includes the disk rotating motor 21, disk clamp hub 22, disk clasper 23, driving lever 24, disk 25, disk roller 26, drive roller 27, and tilting plate cams 32.

[0011] Next, operation of the above disk system will be described.

[0012] To take off either of a plurality of the disks 25 contained in the magazine 19, the magazine 19 is moved in the direction F in the figures by the driving means to be positioned at a desired disk position in the magazine 19.

[0013] The disk 25 slides along a disk guide portion 35 in the magazine 19 by operation of the driving lever 24 in the magazine 19, and a leading end of the disk 25 is bitten between the disk roller 26 and the driven roller 27 of the disk rotating portion 20. Then, the disk 25 is carried to the disk clasper 23 and the disk clamp hub 22 provided on the shaft of the disk rotating motor 21 by turning of the disk roller 26. The clamp position of the disk 25 is checked by a disk detecting means (not shown), and the disk clasper 23 and also the disk roller 26 and the driven roller 27 are moved in the direction of the disk clamp hub 22 by the driving means, to clamp the disk 25.

[0014] At the same time when the driven roller 27 is moved toward the disk clamp hub 22, a pair of the tilting plate cams 32 provided on the disk rotating portion 20 are moved on the magazine 19 side by the driving means, to tilt the tray 31 for forming a suitable space E as shown in Fig. 108b.

[0015] The related art disk system configured as described above requires a magazine case, and consequently, it presents problems that disks cannot be selectively inserted in or ejected from the disk rotating portion one by one and that it is enlarged in size.

[0016] Further, since the related art disk system employs a portable magazine case, it is technically difficult to disassemble racks containing disks from each other in the disk system. As a result, to form a gap between a desired disk to be reproduced and a disk facing to the desired disk, only one-ends of the disks can be opened. In other words, to form a large gap between the disks, a space corresponding to the large gap must be provided in the system, thus causing a problem that the disk system is enlarged in size.

[0017] Further, since the related art disk system employs a portable magazine case, it is very difficult to separate racks containing disks from each other in the disk system while tilting each rack.

[0018] Additionally, to ensure a space in the disk system, there occurs a problem that the disk system is

enlarged in size.

[0019] To solve the above-described problems, the present invention has been made, and an object of the present invention is to provide a disk system capable of being miniaturized, even in the case where the disk system is configured that a plurality of disks are contained without the need of provision of any removable magazine and are each operated, that is, each disk is selectively inserted, ejected, and operated, for example, reproduced.

[0020] Another object of the present invention is to provide a disk system capable of achieving space-saving even in the case where the disk system is configured that a disk containing position is different from a disk reproducing position.

[0021] A further object of the present invention is to provide a disk system capable of preventing a disk being damaged by holding the disk upon insertion or ejection of the disk and moving both roller portions holding the disk upon reproducing or exchange of the disk.

Disclosure of Invention

[0022] The present invention provides a disk system including: first and second disk rollers, provided opposite to each other with a disk carrying path on which a disk is carried put therebetween, for carrying the disk within the disk carrying path while holding both surfaces of the disk; a disk driving means for driving the disk; a first roller moving means for moving, upon operation of the disk driving means, the first disk roller in the direction substantially perpendicular to a plane of the disk opposed to the first disk roller for providing a gap between the first disk roller and the plane of the disk; and a second roller moving means for moving, upon operation of the disk driving means, the second disk roller in the direction substantially perpendicular to the plane of the disk opposed to the second disk roller for providing a gap between the second disk roller and the plane of the disk. With this configuration, it is possible to prevent the disk from being damaged even when the disk is inserted in a gap between the first disk roller and the second disk roller, and hence to improve the reliability of the disk system.

[0023] The first and second roller moving means, preferably, move the first and second disk rollers in such a manner that the first and second disk rollers are opposed to each other. With this configuration, it is possible to accurately insert or eject the disk in or from the disk system and hence to improve the reliability of the disk system.

[0024] Preferably, wherein when an operational state of the disk driving means is switched into a non-operational state, the first and second roller moving means move the first and second disk rollers at positions set before operation of the disk driving means. With this configuration, when a command allowing insertion/ejection of the disk is supplied to the disk system, the inser-

tion/ejection of the disk can be immediately started, resulting in the improved usability of an operator.

[0025] Further, preferably, when the disk inserted in the disk system is ejected out of the disk system, the first and second roller moving means move the first and second disk rollers in such a manner that the first disk roller is brought in contact with either of both surfaces of the disk and the second disk roller is brought in contact with the other of both the surfaces of the disk for holding the disk between the first and second disk rollers. With this configuration, it is possible to accurately eject the disk from the disk system and also prevent the disk from being damaged and hence to improve the reliability of the disk system.

Brief Description of Drawings

[0026]

Fig. 1 is a perspective view showing a schematic configuration of a disk system according to Embodiment 1;

Best Mode for Carrying Out the Invention

Embodiment 1

[0027] The present invention will be described in detail with reference to the accompanying drawings.

[0028] Fig. 1 is a perspective view showing a schematic configuration of an interior of a disk system according to Embodiment 1.

[0029] The disk system is basically divided into the following three mechanism:

[0030] The first mechanism is a disk carrying-in/carrying-out mechanism for carrying a disk inserted in the disk system to and from a specific position; a second mechanism is a disk containing mechanism including a plurality of containing portions for containing disks, wherein upon reproducing of a disk or the like, the containing portions are disposed at specific positions with specific gaps put therebetween; and the third mechanism is a disk holding/reproducing mechanism for holding and reproducing a disk at a specific position.

[0031] Here, a basic operation of the disk system will

be described below.

[0032] First, when the disk carrying-in/carrying-out mechanism carries a disk in the system, the disk containing mechanism is operated, automatically or on the basis of a command, to move a disk containing portion to a position adjacent to the disk carrying-in/carrying-out mechanism and disposed it at the position and to contain the disk in the disk containing portion. At this time, since the disk containing portion is adjacent to the disk carrying-in/carrying-out mechanism, the disk is contained in the disk containing portion only by the operational force of the disk carrying-in/carrying-out mechanism:

[0033] Next, after the disk is contained in the disk containing mechanism, the disk containing portion is moved to the original position and it waits for supply of an operational command such as a reproducing command or it is automatically shifted to the next operation.

[0034] When an operational command such as a reproducing command is supplied to the disk system, the disk holding mechanism and the disk containing mechanism are operated each other, so that the disk containing portion of the disk containing mechanism is moved; while holding the disk, up to a specific operational position, that is, a disk operational position, such as a disk reproducing position, to start the operation of the disk.

[0035] Next, when operation of the disk is completed during operation of the disk, the disk holding/reproducing mechanism and the disk containing mechanism move the disk from the disk operational position into the disk containing mechanism while holding the disk, and it waits for supply of an operational command such as a reproducing command or it is automatically shifted to the next operation.

[0036] Further, when a disk ejection command is supplied to the disk system, the disk containing mechanism moves an automatically selected or designated disk containing portion up to a position adjacent to the disk carrying-in/carrying-out mechanism, and the disk carrying-in/carrying-out mechanism ejects the disk received from the disk containing portion out of the disk system.

[0037] Hereinafter, a general configuration of the disk system carrying out the above-described basic operation will be first described and then the above-described three mechanisms will be described in detail.

[1. General Configuration of Disk system]

[0038] In Fig. 1, reference numeral 100 indicates a housing of a disk system; 101 is a disk insertion port through which a disk is inserted in or ejected from the disk system, that is, the housing 100; and 102 is a disk carrying path along which a disk is carried between the disk insertion port 101 and stockers 501 to 504 (which will be described later).

[0039] Reference numeral 200 indicates a disk loading portion for inserting or ejecting a disk in or from the

housing 100. The disk loading portion 200 includes an upper disk roller, 201 provided at a position facing to a label face of a disk; and a lower disk roller 202 provided at a position opposite to the upper disk roller 201 with the disk put therebetween.

[0040] Reference numeral 300 indicates a disk clamber portion which functions as follows. A disk R, which is pulled in the disk system by the disk loading portion 200 and is once contained in a disk containing mechanism (which will be described later), is placed at a reproducing position on the basis of a command allowing reproducing supplied from an operating portion (not shown). At this time, the disk clamber portion 300 holds the disk R placed at the reproducing position while pressing the disk R from the upper side to a disk reproducing portion 400 (which will be described later).

[0041] The disk clamber portion 300 includes a clamber 301 for press-holding a disk; a clamber arm 302 turnable in the direction C or D to be moved to a disk reproducing position for bringing the clamber 301 in contact with a disk; and a lift arm 303 for holding a knob portion 3012 of the clamber 301 and lifting the clamber 301 upward.

[0042] Reference numeral 400 indicates a disk reproducing portion for rotating a disk and reading-out information stored in the disk. The disk reproducing portion 400 includes a disk turn table, 401 provided with a portion on which a disk is mounted; a disk driving motor 402 for rotating a disk mounted on the disk turn table 401; and a pick-up portion 403 for reading-out information stored in the disk.

[0043] Reference numeral 500 indicates a disk containing mechanism for containing a disk inserted by the disk roller portion 200. The disk containing mechanism 500 is composed of four stockers 501 to 504 (hereinafter, referred to as "first stocker 501, second stocker 502, third stocker 503, and fourth stocker 504) for containing a plurality (four pieces in Embodiment 1) of disks. The stockers 501 to 504 are disposed substantially in parallel to a plane of a disk inserted from the insertion port 101.

[0044] Each of the first stocker 501 to fourth stocker 504 is allowed to contain one disk. The stockers also contains disks in a state in which rotational axial lines of the disks are substantially aligned to each other.

[0045] Hereinafter, each mechanism of the general configuration of the disk system having been schematically described above will be described in detail.

[2. Disk Carrying-in/Carrying-out Mechanism]

[0046] Referring to Figs. 1 and 2, the disk carrying-in/carrying-out mechanism including the disk loading portion 200 functions such that when a disk R is inserted from the insertion port 101, the upper disk roller 201 is rotated in the direction A, that is, counter-clockwise and the lower disk roller 202 is rotated in the direction B; that is, clockwise, to contain the disk R in a

specific stocker adjacent to the disk roller portion 200, for example, in the first stocker 501.

[0047] Although in the above description, the upper disk roller 201 and the lower disk roller 202 are both operated as shown in Figs. 1 and 2, they may be of course operated such that only one roller is rotated and the other roller is slid in contact with a plane of the disk R, that is, not rotated.

[0048] Figs. 2 is a view illustrating a state in which the upper disk roller 201 and the lower disk roller 202 of the disk system shown in Fig. 1 hold a disk therebetween; and Fig. 3 is a view illustrating a state in which the upper disk roller 201 and the lower disk roller 202 of the disk system shown in Fig. 1 release the holding of a disk.

[0049] The disk carrying-in/carrying-out mechanism will be described with reference to Figs. 2 and 3.

[0050] Fig. 2 shows a positional relationship between the upper disk roller 201 and the lower disk roller 202 upon carrying a disk. Here, letting D1 be a gap between both the rollers, the value D1 upon holding of a disk R corresponds to a thickness (1.2 mm) of the disk. With respect to the actual positional relationship

[0051] with the disk R, the state upon holding of the disk R is shown in Fig. 4, and the state upon release of the disk R is shown in Fig. 5.

[0052] Next, a configuration of a mechanism of operating the disk roller portion 200, and operation of the upper disk roller 201 and the lower disk roller 202 will be described in detail with reference to Fig. 6a to Fig. 9d.

[0053] Figs. 6a to 6d are front views of essential portions, each showing a configuration and an operational state of a front surface portion of the disk roller portion 200; Figs. 7a to 7d are top views of essential portions, showing a configuration and an operational state of an upper surface of the disk roller portion 200; Figs. 8a to 8d are side views of the upper disk roller 201 showing a configuration and an operational state of a side surface of the upper disk roller 201; and Figs. 9a to 9d are side views of the lower disk roller 202 showing a configuration and an operational state of a side surface of the lower disk roller 202. In addition, Figs. 8a and 8d and Figs. 9a to 9d show left side surfaces of the upper and lower disk rollers 201 and 202 in Embodiment 1, respectively.

[0054] Each of Figs. 6a, 7a, 8a and 9a shows a state in which the disk R is not inserted; each of Figs. 6b, 7b, 8b and 9b shows a state in which the disk R is moved to be inserted and carried, that is, the disk R is held; each of Figs. 6c, 7c, 8c, and 9c shows a state being in the course of extending a gap between the upper disk roller 201 and the lower disk roller portion 202 at maximum, in which the gap is extended for placing the disk R in the gap so as to move the disk R to a reproducing position; and each of 6d, 7d, 8d and 9d shows a state in which the disk R is placed in the gap extended at maximum and is reproduced. That is, these figures show the process from the state in which the gap between both the rollers is minimized to the state in which the gap is max-

imized and the process from insertion of the disk R to reproducing of the disk R in the order of the states shown in Figs. 6a, 7a, 8a and 9a → Figs. 6b, 7b, 8b and 9b → Figs. 6c, 7c, 8c and 9c → Figs. 6d, 7d, 8d and 9d.

[0055] Reference numeral 203 indicates a roller open cam plate for adjusting a magnitude of a gap between the upper disk roller 201 and the lower disk roller 202. The roller open cam plate 203 is composed of a main body 2031 and a cam portion 2032.

[0056] Here, the main body 2031 of the roller open cam plate 203 has a sliding hole 20311 at one end on the upper disk roller 201 side or the lower disk roller 202 side, and a sliding hole 20312 at the other end. The sliding hole 20311 allows a sliding shaft composed of a base pin (not shown) provided in the housing 100 to slid therein in the direction A or B. The sliding hole 20312 allows a pin 2092 of a link portion 209 (both will be described later) to be slid therein in the direction C or D.

[0057] The cam portion 2032 of the roller open cam plate 203 has a tilting sliding hole 20321 and a tilting portion 20322. The sliding hole 20321 allows a pin 2041 provided on part of an upper roller arm 204 (both will be described later) to be slid therein. The tilting portion 20322 allows a pin 2022 formed at a leading end of the lower disk roller 202 to be brought in contact with part of a peripheral edge portion of the cam portion 2032.

[0058] Reference numeral 204 is the upper roller arm for holding one end 2011 of the upper disk roller 201. The upper roller arm 204 has the pin 2041 slid in the sliding hole 20321 of the cam portion 2032 of the roller open cam plate 203, and also has a shaft holding hole 2042 in which the base pin (not shown) provided in the housing 100 is fitted.

[0059] In this case, the one end 2011 of the upper disk roller 201 is formed separately from the pin 2041; however, the pin 2041 may be substituted for the one end 2011.

[0060] Reference numeral 205 indicates a lower roller arm having at its one end a lower roller holding portion 2051 and at the other end a shaft holding hole 2052. The lower roller holding portion 2051 holds part of an extension portion 2022 having a shaft portion formed at a leading end of the lower disk roller 202. In the shaft holding hole 2052 is fitted the base pin (not shown) provided in the housing 100.

[0061] Reference numeral 206 indicates an open link having at one end a pin 2061 fitted in the sliding hole 20312, a shaft holding hole 2062 in which the base pin (not shown) provided in the housing 100 is fitted, and at a peripheral edge of part of the other end a sliding contact portion 2063 with which a slider 304 (which will be described later) is brought in contact.

[0062] Next, operation of the above-described disk carrying-in/carrying-out mechanism will be described.

[0063] First, as shown in Figs. 6a, 7a, 8a and 9a, when the disk R is not inserted, the slider 304 is positioned on the insertion port 101 side, that is, on the B side, and the pin 2061 of the open link 206 is positioned

on the D side.

[0064] At this time, since the pin 2041 of the upper roller arm 204 is positioned at the left end in the sliding hole 20321 as shown in Fig. 8a, the position of the upper disk roller 201 is not changed and the position of the upper roller arm 204 is not changed.

[0065] The extension portion 2022 of the lower disk roller 202 held by the lower roller holding portion 2051 is usually biased on the upper disk roller 201 side by an elastic member (not shown) because the position of the roller open cam plate 203 is not changed. As a result, the extension portion 2022 is brought in contact with the tilting portion 20322 at a position closest to the upper disk roller. That is, the lower disk roller 202 is located at such a position.

[0066] In this case, the closest gap between the upper disk roller 201 and the lower disk arm 202 is set to be slightly thinner (for example, 0.5 mm) than a general thickness (for example, 1.2 mm) of the disk R in order to absorb a variation in thickness of disks and to ensure a sufficient disk holding pressure for preventing a disk from being slipped off from the gap between the rollers.

[0067] Next, in the case where the disk R is inserted from the insertion port 101 in the above-described operational state, as shown by the operational states in Figs. 6b, 7b, 8b and 9b, since the closest gap between the upper disk roller 201 and the lower disk roller 202 is set to be thinner than the thickness of the disk as described above, the gap is opened to a value corresponding to the thickness of the disk as the disk is pulled in by rotation of the rollers or the like.

[0068] Other operations are similar to those described with reference to Figs. 6a, 7a, 8a and 9a, and therefore, the explanation thereof is omitted.

[0069] The disk R, which is inserted by the operations shown in Figs. 6b, 7b, 8b and 9b and is contained in a stocker once, is operated as shown by the operating states in Figs. 6c, 7c, 8c and 9c when a command allowing reproducing of the disk R is supplied by the operating portion (not shown).

[0070] Figs. 6b, 7b, 8b and 9b each show the state being in the course of opening the rollers when the disk reproducing portion 400 is moved up to the disk reproducing position, particularly, a state being in the course of moving in the direction A the slider 304 connected to move the disk reproducing portion 400.

[0071] The slider 304 has contact portions 3041 and 3042 to be brought in contact with the contact portion 2063 provided on the open link 206. As shown in Fig. 7c, since the link portion 206 is rotated in the direction C around the shaft (not shown) fitted in the shaft holding hole 2062 along with movement of the slider 304 in the direction A, the pin 2061 of the link portion 206 is slid in the sliding hole 20312 of the roller open cam plate 203 in such a manner as to be rotated in the direction C.

[0072] In addition, since the roller open cam plate 203 is moved only in the direction A or B, of the rotating force of the open link 206 in the direction C, only a movement

component in the direction A is transmitted to the roller open cam plate 203 to move the roller cam plate 203.

[0073] Further, as described above, since the roller open cam plate 203 is moved in the direction A, that is, moved in the direction E as shown in Fig. 8c, the upper roller arm 204, that is, the upper disk roller 201 held by the upper roller arm 204 is moved in the direction G because the pin 2041 is slid in the sliding hole 20321 of the roller open cam plate 203 in the direction F and the sliding hole 20321 moving in the direction F moves the upper roller arm 204 in the direction G.

[0074] Further, as described above, since the roller open cam plate 203 is moved in the direction A, that is, moved in the direction I as shown in Fig. 9c, the lower roller arm 205 is pressed to the peripheral portion of the extension portion 2022 of the lower disk roller 202 in the direction K, that is, rotated in the direction K around the shaft (not shown) fitted in the shaft holding hole 2052, and accordingly, the lower roller arm 205 is rotated in the direction K along the tilting portion 20322 of the roller open cam plate 203 and thereby the lower disk roller 202 held by the lower roller arm 205 is moved in the direction K.

[0075] Accordingly, as shown in Fig. 6c, the gap can be set at a value d3 in accordance with operation of the slider 304.

[0076] Finally, when the slider 304 is moved, from the operational states shown in Figs. 6c, 7c, 8c and 9c, in the direction A shown in Fig. 7c, the operational states of the disk R upon reproducing of the disk R become those shown in Figs. 6d, 7d, 8d and 9d. Since the slider 304 is further moved in the direction A as shown in Fig. 7d, the open link 206 is further rotated in the direction C from the state shown in Fig. 7c to thereby further move the roller open cam plate 203 in the direction A.

[0077] Further, during movement of only the slider 304 in the direction A in a state in which the slider contact portion 2063 of the open link 206 is positioned in parallel to the contact portion of the slider 304 as shown in the figures, the open link 206 is no longer moved in the direction C, and even if the open link 206 is applied with a force for returning the opening link 206 in the direction d, the slider 304 is not applied with a force for returning the slider 304 in the direction B.

[0078] Accordingly, the roller open cam plate 203 is held at a final position in the direction A.

[0079] At this time, as shown in Fig. 8d, the pin 2041 of the upper roller arm 204 is slid in the sliding hole 20321 of the roller open cam plate 203 up to a position near the terminal on the F side, and the upper disk roller 201 is further moved in the direction G and is held at such a position.

[0080] Further, since the slider 304 is further moved in the direction A as shown in Fig. 7d, the tilting portion 20322 of the roller open cam plate 203 presses and moves the extension portion 2022 of the lower disk roller 202 in the direction K up to the terminal portion in the direction J as shown in Fig. 9d, so that the lower disk

roller 202 is further moved in the direction K and is held at such a position.

[0081] The disk carrying-in/carrying-out mechanism having the above configuration can perform a series of operations shown in Figs. 6a to 6d.

[0082] It is assumed that a gap between the upper disk roller 201 and the lower disk roller 202 upon non-insertion of a disk as shown in Fig. 6a is taken as d1. In this case, when a disk having a thickness d2 is inserted as shown in Fig. 6b, the thickness d2 of the disk becomes the gap. Next, since the roller open cam plate 203 is moved in the direction of carrying the disk R for making preparation of reproducing the disk as shown in Fig. 6c, the upper disk roller 201 is started to be moved upward and the lower disk roller 202 is started to be moved downward for enlarging the gap. The gap in such a state is taken as d3. When the disk is started to be reproduced from the state of making preparation of reproducing of the disk shown in Fig. 6c, the gap is further extended as shown in Fig. 6d. The gap in such a state is taken as d4.

[0083] In summary, the change in gap from the state shown in Fig. 6a to the state shown in Fig. 6d is expressed by a relationship of $d1 < d2 < d3 < d4$.

[0084] In the case of stopping reproducing of the disk R and ejecting the disk R, that is, in the case of performing operations reversed to those described above, the disk carrying-in/carrying-out mechanism is operated in the order of the states shown in Figs. 6d, 7d, 8d and 9d → Figs. 6c, 7c, 8c and 9c → Figs. 6b, 7b, 8b and 9b → Figs. 6a, 7a, 8a and 9a.

[3. Disk Holding/Reproducing Mechanism]

[0085] A disk holding/reproducing mechanism basically includes a disk clasper portion 300 for holding a disk by pressing down the disk; a disk reproducing portion 400 for mounting, rotating and reproducing a disk; and a moving mechanism portion for moving both the disk clasper portion 300 and the disk reproducing portion 400. A disk driving means is mainly constituted of the disk reproducing portion 400.

[0086] Hereinafter, the disk clasper portion 300 will be first described in detail, and then the disk reproducing portion 400 will be described in detail.

[3-1. Disk Clasper Portion]

[0087] A configuration of the disk clasper portion 300 will be described with reference to Figs. 10a and 10b, and Figs. 11a and 11b.

[0088] Figs. 10a and 10b are views showing a configuration of the disk clasper portion 300 and its peripheral members, wherein Fig. 10a is a top view, and Fig. 10b is a sectional front view of Fig. 10a.

[0089] Figs. 11a and 11b are views showing an essential portion shown in Figs. 10a and 10b, wherein Fig. 11a is a sectional right side view, and Fig. 11b is a view

illustrating a shape of a slider seen from the left side of the slider.

[0090] In Figs. 10a and 10b, and Figs. 11a and 11b, reference numeral 301 indicates a clasper. The clasper 301 includes at a portion opposite to a disk plane a contact portion 3011 to be brought in contact with a disk; and a knob portion 3012 to be hooked up by a hook portion 3031 (which will be described later) of the lift arm 303.

[0091] Reference numeral 302 indicates a clasper arm for supporting the clasper 301. The clasper 302 includes a shaft holding hole 3021 in which a shaft portion 3061 (which will be described later) provided on a base portion 306 is rotatably inserted; a pin 3022 slidably inserted in a sliding hole 3034 (which will be described later) formed in the lift arm 303; and a sliding hole 3023 in which a pin 3051 (which will be described later) formed in the link portion 305 is slidably inserted.

[0092] Reference numeral 303 indicates the lift arm for supporting the clasper portion 301. The lift arm 303 is usually biased upward by a spring 307 (which will be described later). The lift arm 303 includes the hook portion 3031 for hooking up the knob portion 3012 provided on the clasper 301; a shaft holding portion 3032 for allowing the lift arm 303 to be turned therearound with respect to the clasper arm 302; a sliding hole 3033 in which the shaft portion 3061 (which will be described later) provided on the base portion 306 is turnably inserted; the sliding hole 3034 in which the pin 3022 provided on the clasper arm 302 is slid; and a sliding hole 3035 in which the pin 3051 (which will be described later) formed on the link portion 305 is slidably inserted.

[0093] Reference numeral 304 indicates the slider. One end 3041 of the slider 304 is connected to the base portion 306 (which will be described later) so that the slider 304 is moved in the direction A or B. A pin 3042 is provided at the other end of the slider 304, and is slidably inserted in a sliding hole 3053 (which will be described in later) of the link portion 305.

[0094] Reference numeral 305 indicates the link portion which includes the pin 3051 slidably inserted in the sliding hole 3023 of the clasper arm 302 and in the sliding hole 3035 of the lift arm 303; a shaft holding hole 3052 for allowing the link portion 305 to be turned therearound with respect to the base portion 306 (which will be described later); and the sliding hole 3053 in which the pin 3042 provided on the slider 304, is slidably inserted.

[0095] Reference numeral 306 indicates the base portion provided in the vicinity of the disk roller portion 200 in such a manner as to be approximately parallel to the stoker 501 in a state containing no disk. The base portion 306 includes the shaft 3061 inserted in the shaft holding hole 3021 of the clasper 302 and the sliding hole 3035 of the lift arm 303; and a contact portion 3062 which is brought in contact with the one end 3041 of the slider 304 to move the slider 304.

[0096] Reference numeral 307 indicates the biasing

portion formed of a spring. One end of the biasing portion 307 is connected to the clasper arm 302, and the other end of the biasing portion 307 is connected to the lift arm 303.

[0097] Next, operation of the disk clasper portion 300 will be described with reference to Fig. 10a to 16c.

[0098] Figs. 10a and 10b and Figs. 11a and 11b are views showing a state in which a command allowing reproducing is not supplied from the operating portion; Figs. 12a and 12b are views showing a state in which a command allowing reproducing is supplied from the operating portion so that the disk mounting portion 400 is started to be moved in the direction A and the disk clasper portion 300 is started to be moved in the direction A along with the movement of the disk mounting portion 400; Figs. 13a and 13b are views showing a state in which the disk clasper portion 300 is moved from the state shown in Figs. 12a and 12b up to the vicinity of the reproducing position of a disk; Figs. 14a and 14b are views showing a state in which the disk clasper portion 300 is brought in contact with the disk R; and Figs. 15a and 15b are views showing a state in which the disk can be reproduced.

[0099] Figs. 10a is a top view showing a configuration, and Fig. 10b is a front view of Fig. 10a; and Fig. 11a is a side view of the configuration shown in Figs. 10a and 10b, and Fig. 11b is a view showing an essential portion shown in Figs. 10a and 10b.

[0100] Figs. 12a, 13a, 14a and 15a are top views each showing an operational state; and Figs. 12b, 13b, 14b and 15b are side views of Figs. 12a, 13a, 14a and 15a, respectively.

[0101] Figs. 16a to 16c are views showing operational states of an essential portion of the disk clasper portion 300, wherein Fig. 16a shows a state in which no disk is mounted; Fig. 16b shows a state in which the disk clasper portion 300 is brought in contact with a disk; and Fig. 16c shows a state in which the disk is held between the disk clasper portion 300 and the disk mounting portion 400.

[0102] First, in a state in which a command allowing reproducing is not supplied from the operating portion (not shown), the disk reproducing portion 400 (operation thereof will be described later) is not moved, so that the clasper arm 302 movable through the slider 304 and the link portion 305 based on the movement of the disk reproducing portion 400 is not moved. As a result, the state shown in Figs. 10a and 10b and Figs. 11a and 11b is kept.

[0103] Next, when a command allowing reproducing is supplied from the operating portion, the disk reproducing portion is started to be moved in the direction A, and the slider 304 connected to part of the disk mounting portion is also moved in the direction A (which will be described in detail later).

[0104] At this time, the pin 3042 provided on one end of the slider 304 is similarly moved in the direction A in the sliding hole 3053 of the link portion 305. As a result,

the link portion 305 is rotated in the direction B around the shaft portion 3052 of the link portion 305, so that the clasper arm 302 and the lift arm 303 are rotated in the direction C around the shaft portion 3061 through the pin 3051 of the link portion 305.

[0105] After the operation shown in Figs. 12a and 12b, the stocker 501 containing the disk R is moved in the direction D as shown in Figs. 13a and 13b, and the stocker 503 waits at the reproducing position of the disk R.

[0106] In addition, a configuration and an operation of the stocker will be described in detail later.

[0107] Next, as shown in Figs. 14a and 14b, the disk reproducing portion 400 is moved again in the direction A and the slider 304 is moved up to the A side terminal portion of the contact portion 3062 formed on the base portion 306 along with the movement of the disk reproducing portion 400. As a result, the clasper arm 302 and the lift arm 303 are disposed at the reproducing position of the disk R in association of the above-described operation of the slider 304.

[0108] Then, as shown in Figs. 14a and 14b, the hook portion 3031 of the lift arm 303 is separated from the knob portion 3012 held by the clasper arm 302, and the contact portion 3011 of the clasper 301 is brought in contact with the surface of the disk, to thereby hold the disk in cooperation of the turn table 401 of the disk reproducing portion 400 which supports the back surface of the disk.

[0109] Further, after completion of the operation shown in Figs. 14a and 14b, to reproduce the disk R, the stocker 501 is moved in the direction A to the original position as shown in Figs. 15a and 15b, to thus reproduce the disk R.

[0110] Here, there will be briefly described the state in which the disk R is held between the clasper 301 and the turn table 401 of the disk reproducing portion 400 with reference to Figs. 16a to 16c.

[0111] First, in the case where the disk R is not disposed at the reproducing position as shown in Fig. 16a, the clasper arm 302 is moved to the reproducing position of the disk R and is also pulled up in the direction E by the lift arm 303 for allowing the disk R to be easily inserted in a gap d1 between the clasper 301 and the turn table 401.

[0112] Next, when the clasper arm 302 is disposed at the reproducing position of the disk R and the disk R is also disposed at the reproducing position as shown in Fig. 16b, the lift arm 303 is moved in the direction F to release the knob portion 3012 of the clasper 301, so that the contact portion 3011 of the clasper 301 biased in the direction G is brought in contact with the surface of the disk R.

[0113] In such a state, the gap (d2) becomes smaller than the gap d1 shown in Fig. 16a.

[0114] Further, since an attracting force is generated between a surface 30111 to be magnetized, which is provided on the contact portion 3011 of the clasper

301, and a magnet 40111 provided on a disk mounting portion 4011 of the turn table 401 as shown in Fig. 16c, the clasper 301 is attracted on the turn table 401, to thereby hold the disk R. In such a state, the gap (d3) is nearly equal to the thickness D of the disk R ($d3 \approx D$).

[0115] In addition, in the case where the reproducing of the disk is completed and the disk R is contained in the disk containing mechanism 400, the disk clasper portion 300 is operated in accordance with operations reversed to those described above, that is, in the order of the states shown in Figs. 15a and 15b → Figs. 14a and 14b → Figs. 13a and 13b → Figs. 12a and 12b → Figs. 10a, 10b, 11a and 11b.

[3-2. Disk Reproducing Portion]

[0116] Next, a configuration of the disk reproducing portion 400 will be described with reference to Figs. 17a and 17b.

[0117] Figs. 17a and 17b are views showing a configuration of the disk reproducing portion 400, wherein Fig. 17a is a top view and Fig. 17b is a sectional front view taken on line XVII-XVII of Fig. 17a.

[0118] In Figs. 17a and 17b, reference numeral 401 indicates the turn table for rotating a disk. The turn table 401 includes a disk mounting portion 4011 and a projecting portion 4012 to be inserted in a center hole of a disk for holding the disk. The magnet 40111 is provided on the disk mounting portion 4011.

[0119] Reference numeral 402 indicates an optical pick-up driving portion for moving in the direction A an optical pick-up portion 403 for reading-out information recorded in a disk; 404 is an optical pick-up guiding portion for guiding the optical pick-up portion 403 in the direction A; and 405 is an optical pick-up feed screw turnable in the direction C or D on the basis of a driving force of the optical pick-up driving portion 402.

[0120] The optical pick-up portion 403 includes a pick-up 4031 for emitting a light source to a disk and reading-out information recorded in the disk; supporting portions 4032 and 4033 for supporting the optical pick-up guiding portion 404 in such a manner as to move the optical pick-up portion 403 in the direction A or B; and a screw portion 4034 to be screwed with a threaded portion of the optical pick-up feed screw portion 405.

[0121] When the optical pick-up feed screw portion 405 is rotated in the direction C or D on the basis of a rotating force of the optical pick-up driving portion 402, the screw portion 4034 converts the rotating force of the optical pick-up feed screw portion 405 into the movement in the direction A or B, to thereby move the optical pick-up portion 403 in the direction A or B.

[0122] Next, there will be described a configuration of an operating mechanism for operating the above-described disk reproducing portion 400 in the disk system with reference to Figs. 18a and 18b.

[0123] Figs. 18a and 18b are views showing a configuration of a moving mechanism portion 450 for moving

the disk reproducing portion 400 in the direction A or B. In these figures, there is shown a state in which the disk R is contained in the stocker 501.

[0124] In addition, Fig. 18a is a top view and Fig. 18b is a sectional front view.

[0125] In Figs. 18a and 18b, reference numeral 450 indicates the moving mechanism portion for moving the disk reproducing portion 400 shown in Figs. 17a and 17b. The moving mechanism portion 450 includes a base portion 451, a base driving portion 452, a motor 453, a gear portion 454, a plate guide 455, a slider 456, a first link portion 457, a second link portion 458, and a shaft portion 459.

[0126] In addition, the slider 304 is connected to the slider 456 to be integrated therewith.

[0127] Next, the functions of the above components will be described in detail.

[0128] First, reference numeral 451 indicates the base portion which is fixed to the base portion 306 and is connected to the disk reproducing portion 400 for supporting it and which is also movable in the direction E or F; 452 is the base driving portion for moving the slider 456 (which will be described later) in the direction E or F; 453 is the motor for moving the disk roller portion 200, disk clasper portion 300 and disk reproducing portion 400; and 454 is the gear portion for transmitting the rotating force of the motor 453 to the slider 456 (which will be described later).

[0129] Reference numeral 455 indicates the plate guide which is fixed on the base 451 and which has a groove for guiding the slider 456 and the disk reproducing portion 400; and 456 is the slider screwed with the gear portion 454 and moved in the direction E or F along with turning of the gear portion 454. The above slider 456 is part of the slider 456 slidably mounted on the plate guide 455 and the base 451.

[0130] Reference numeral 457 indicates the first link portion having at one end a pin 4571 slidably inserted in a sliding hole 4562 provided in part of the slider 456 and also having at the other end a shaft portion 4572 turnably fixed on the base portion 451; 458 is the second link portion having at one end a shaft portion 4581 for turnably supporting the slider 456 and also having at the other end a pin 4582 slidably inserted in a sliding hole 4511 formed in part of the base portion 451; and 459 is the shaft portion for connecting the first link portion 457 to the second link portion 458 and turnably supporting the first link portion 457 and the second link portion 458.

[0131] Next, operation of the moving mechanism portion 450 will be described with reference to Figs. 18a to Fig. 28c.

[0132] As described above, Figs. 18a and 18b show the state in which a command allowing reproducing is not supplied from the operating portion and thereby the disk reproducing portion 400 is not operated. As shown in Figs. 18a and 18b, the slider 456, first link portion 457, and second link portion 458 are disposed at positions closest to the insertion port 101.

[0133] Here, Fig. 19 shows a state in which the disk reducing portion 400 shown in Figs. 17a and 17b is mounted on the operating mechanism shown in Figs. 18a and 18b. In such a state, the disk reproducing portion 400 is not superimposed on the disk R contained in the stocker 501.

[0134] Figs. 20a and 20b are views showing a left side surface of the mechanism shown in Figs. 18a and 18b and Fig. 19, wherein Fig. 20a is a side view and Fig. 20b is an illustrative view of Fig. 20a.

[0135] Next, when a command allowing reproducing is supplied to the disk system, the motor 453 is driven, and a driving force is transmitted to the slider 456 through the gear to move the slider 456 in the direction F, so that the disk reproducing portion 400 connected to the slider 456 is also moved in the direction F. Such a state is shown in Fig. 21.

[0136] In such a state, the disk roller mechanism 200 is opened up and down by the above-described mechanism as shown in Fig. 12b, to allow entrance of the disk R.

[0137] Further, the stocker 501 is moved in the direction E and the disk R is moved from a position R1 to a reproducing position R2.

[0138] Fig. 22 shows a state in which the disk reproducing portion 400 is mounted on the state shown in Fig. 21.

[0139] The movement of the disk reproducing portion 400 is further progressed up to the reproducing position of the disk, and when the movement thereof is completed, the disk is held between the disk clasper portion 300 and the disk reproducing portion 440, to thus start reproducing of the disk R.

[0140] Such a state is shown in Figs. 23a and 23b. In addition, Fig. 24 shows a state in which the disk reproducing portion 400 is mounted on the state shown in Figs. 23a and 23b.

[0141] In Figs. 23a and 23b and Fig. 24, the motor 453 is further driven to move the slider 456 through the gear portion 454 in the direction E.

[0142] In this way, the slider 456 is further moved in the direction E, and thereby the pin 4571 of the first link portion 457 is further slid in the sliding hole 4562 of the slider 456 in the direction G; however, when reaching an end portion of the sliding hole 4562 on the slider 304 side, the pin 4571 is prevented from being further moved in the direction G.

[0143] Like the pin 4571 of the first link portion 457, the pin 4582 of the second link portion 458 is further slid in the sliding hole 4511 of the base portion 451 in the direction G; however, when reaching an end portion of the sliding hole 4511 on the slider 304 side, the pin 4582 is prevented from being further moved in the direction G.

[0144] As a result, the movement of the first link portion 457 and the second link portion 458 are prevented, and the portions at which the movement of the link portions 457 and 458 is stopped are set at positions of

reproducing the disk R. Thus, the link portions 457 and 458 can be easily set at the disk reproducing positions.

[0145] Figs. 25a to Figs. 28c are sectional views of right and left sides of essential portions, showing the above operations.

[0146] Figs. 25a to 25c are sectional left side views, wherein Fig. 25a shows a state in which the state shown in Figs. 10a and 10b is assembled with the state shown in Fig. 19; Fig. 25b shows a state in which the state shown in Figs. 12a and 12b is assembled with the state shown in Fig. 22; and Fig. 25c shows a state in which the state shown in Figs. 13a and 13b is assembled with the state shown in Fig. 24.

[0147] Figs. 26a to 26c are sectional left side views, wherein like Figs. 25a to 25c, Fig. 26a shows a state in which the state shown in Figs. 10a and 10b is assembled with the state shown in Fig. 19; Fig. 26b shows a state in which the state shown in Figs. 12a and 12b is assembled with the state shown in Fig. 22; and Fig. 26c shows a state in which the state shown in Figs. 13a and 13b is assembled with the state shown in Fig. 24.

[0148] Figs. 27a to 27c are sectional right side views, wherein Fig. 27a shows a state in which the state shown in Figs. 10a and 10b is assembled with the state shown in Fig. 19; Fig. 27b shows a state in which the state shown in Figs. 12a and 12b is assembled with the state shown in Fig. 22; and Fig. 27c shows a state in which the state shown in Figs. 13a and 13b is assembled with the state shown in Fig. 24.

[0149] Figs. 28a to 28c are sectional right side views, wherein like Figs. 27a to 27c, Fig. 28a shows a state in which the state shown in Figs. 10a and 10b is assembled with the state shown in Fig. 19; Fig. 28b shows a state in which the state shown in Figs. 12a and 12b is assembled with the state shown in Fig. 22; and Fig. 28c shows a state in which the state shown in Figs. 13a and 13b is assembled with the state shown in Fig. 24.

[4. Disk Containing Mechanism]

[0150] Next, the disk containing mechanism will be described.

[0151] The disk containing mechanism 500 basically includes the stocker portions 501 to 504; a driving mechanism portion 510 driven for moving the stockers 501 to 504; and a moving mechanism portion 520 for giving a specific movement to each of the stockers 501 to 504 at each specific stage on the basis of a driving force of the driving mechanism portion 510.

[0152] In addition, a stocker moving means is composed of the driving mechanism portion 510 and the moving mechanism portion 520.

[0153] First, a configuration of the first stocker portion will be described with reference to Figs. 29 and 30.

[0154] Fig. 29 is an exploded view of an essential portion of the disk containing mechanism 500, and Fig. 30 is a view showing a state in which components of the essential portion shown in Fig. 29 are assembled.

[0155] In the following description of the stocker portion as the essential portion, the stocker portion is represented by the first stocker 501 positioned at the uppermost stage.

[0156] In Figs. 29 and 30, the first stocker 501 includes a containing portion 5011 for containing a disk; a stopper 5012 for preventing a disk contained in the containing portion 5011 from being moved in the direction A; a locking portion 5013 for locking a peripheral edge of a disk contained in the containing portion 5011, thereby preventing the disk from being moved in the direction B; a projecting portion 5014 formed on the stocker 501 in such a manner as to be fitted in a fitting hole 50131 formed in the locking portion 5013 and turnable around the fitting hole 50131; a biasing portion 5015 engaged with an engaging portion 50134 of the locking portion 5013 for usually biasing the locking portion 5013 in the direction C; and a holding portion 5016 fitted in a fitting hole 5017 formed in the stocker 501 for holding the biasing portion 5015.

[0157] Further, a rail sliding portion 5018 is formed on part of a peripheral edge portion of the stocker 501, and as shown in Fig. 31, the rail sliding portion 5018 is slidably inserted in a rail portion 5019.

[0158] Next, operation of the first stocker 501 described above will be described with reference to Figs. 31 and 32.

[0159] Here, Fig. 31 is a view showing a state in which the first stocker 501 contains the disk R, that is, in a state in which the disk R is inserted and is contained in the first stocker 501, and the first stocker 501 is moved to a specific position; and Fig. 32 shows a state in which the first stocker 501 is moved in the direction B, that is, in a state in which the disk R is contained in or ejected from the containing portion 5011 of the first stocker 501.

[0160] As shown in Fig. 31, when the stocker 501 containing the disk R is located at a specific position, if an external disturbance for moving the disk R in the direction B and ejecting it from the containing position is applied to the disk R, a rotational force in the direction E is given from the disk R to the locking portion 5013; however, since the rail contact portion 50133 provided on the locking portion 5013 is brought in contact with the rail portion 5019, the rotation of the locking portion 5013 is prevented. As a result, the locking portion 5013 holds the disk R, and prevents movement of the disk R.

[0161] Next, when the disk R is carried or reproduced, that is, the disk is delivered to the disk loading portion 100 or delivered to the disk mounting portion 400 for reproducing of the disk R, prevention of the movement of the disk R shown in Fig. 31 must be released.

[0162] In this case, as shown in Fig. 32, by moving the first stocker 501 in the direction B, the rail portion 5019 is separated from the rail contact portion 50133 provided on the locking portion 5013, to release prevention of rotation of the locking portion 5013 in the direction E, thereby releasing holding of the disk R by the locking portion 5013.

[0163] Here, a relationship between motions of the disk carrying-in/carrying-out mechanism 100, disk mounting portion 400, and disk containing mechanism 500 will be briefly described with reference to Figs. 33 to 35.

[0164] Fig. 33 is a view showing a state in which the disk R is inserted and contained in the first stocker 501 or it is ejected from the first stocker 501, Fig. 34 is a view showing a state in which the disk R contained in the first stocker 501 is moved to a reproducing position and the disk mounting portion 400 is moved to the reproducing position; and Fig. 35 is a view showing a state in which the first stocker 501 is returned to the containing position and the disk R is reproduced.

[0165] First, as shown in Fig. 33, when the disk R is inserted from the insertion port (not shown), the rail sliding portion 5018 is slid in the direction A with respect to the rail portion 5019 supported by the housing 100 so that the first stocker 501 projects in the direction A.

[0166] At this time, the locking portion 5013 is rotatable in the direction B because the rail portion 5019 is not brought in contact with the rail contact portion 50133.

[0167] Accordingly, the disk R rotates the locking portion 5013 in the direction B against a biasing force of the biasing portion 5015 by the rotating force of the upper disk roller 201, to be thus smoothly contained in the containing portion 5011 of the first stocker 501.

[0168] Next, as shown in Fig. 34, when a command allowing reproducing of the disk R is supplied from the operating portion (not shown), the disk mounting portion 400 is moved in the direction B and is set at a position 400B shown by a broken line.

[0169] The state in which the above setting is completed is shown in Fig. 35.

[0170] Next, the driving mechanism portion 510 will be described with reference to Fig. 36.

[0171] Fig. 36 is a top view showing the driving mechanism portion and its peripheral configuration.

[0172] The driving mechanism portion 510 is a mechanism for moving the stockers 501 to 504 in the vertical direction or the direction C or D by operating each arm portion, and for moving the base portion 451 in the vertical direction.

[0173] The mechanism for moving the first stocker 501 to the fourth stocker 504 in the direction C or D may be provided on the base portions 306 and 451.

[0174] In Fig. 36, reference numeral 511 is a cam portion which is rotated in the direction A or B around a rotating shaft 5111 on the basis of driving of a driving portion (not shown) provided on the housing 100. An outer peripheral sliding hole 5112 is formed in an outer peripheral surface of the cam portion 511, and an inner peripheral sliding hole 5113 is formed in an inner peripheral surface of the cam portion 511.

[0175] Reference numeral 512 indicates a first arm portion which includes a shaft portion 5121 turnably supported by a portion (not shown) of the housing 100 located at a higher position; a pin 5122 connected to

one end of a second cam plate (which will be described later); and a pin 5123 connected to the other end of the second cam plate; and a pin 5124 slidably inserted in the outer peripheral sliding hole 5112 of the cam portion 511.

[0176] The disk reproducing portion 400 has a mechanism in which the base portion 451 contained in and connected to the disk reproducing portion 400 is moved in the vertical direction.

[0177] The mechanism for moving the first stocker 501 to the fourth stocker 504 in the direction C or D may be provided on the base portions 306 and 451.

[0178] Reference numeral 513 indicates a second arm portion turnable around a shaft portion 5131. One side of the second arm portion 513 is branched into a cam arm 5132 and a plate arm 5133. At one end of the cam arm 5132 is formed a pin 51321 slidably inserted in the inner peripheral sliding hole 5113 of the cam portion 511. At one end of the plate arm 5133 is formed a pin 51331 connected to one end of the first cam plate (which will be described later). At a portion of the plate arm 5133 is formed a pin 51332 slid in a sliding hole 5143 (which will be described later) of a third arm portion 514.

[0179] Further, the other side of the second arm portion 513 has a pin 5134 connected to the other end of the first cam plate; a pin 5135 slid in a sliding hole 5153 (which will be described later) of a fourth arm portion 515; and a hole 5136 for preventing the contact with a turning shaft 5151 (which will be described later) of the fourth arm portion 515.

[0180] Reference numeral 514 indicates the third arm portion which is formed in such a manner as to be turnable around a turning shaft 5141. One end of the third arm portion 514 has a pin 5142 connected to one end of the third cam plate (which will be described later) and the sliding hole 5143 in which the pin 51332 of the second arm portion 512 is slid.

[0181] Reference numeral 515 indicates the fourth arm portion which is formed in such a manner as to be turnable around a rotating shaft 5151. One end of the fourth arm portion has a pin 5152 connected to one end of the third cam plate (which will be described later) and the sliding hole 5153 in which the pin 5135 of the second arm portion 512 is slid.

[0182] The above-described cam portion 511, first arm portion 512, second arm portion 513, third arm portion 514, and fourth arm portion 515 constitute the driving mechanism portion 510.

[0183] With the driving mechanism portion 510 having the above configuration, the first arm portion 512 to the fourth arm portion 515 are moved in the direction C or D by a turning force of the cam portion 511, and thereby they can be set at desired positions on the basis of a turning angle of the cam portion 511.

[0184] Next, the moving mechanism portion 520 will be described with reference to Figs. 37a to 38g.

[0185] Figs. 37a is a sectional top view showing an

essential portion of the moving mechanism portion 520; and Fig. 37a and Figs. 38a to 38g are side views seen from the direction A in Fig. 37a showing all of the members of the moving mechanism portion 520.

[0186] The moving mechanism portion 520 is a mechanism for adjusting a height of each of the first stocker to the fourth stocker, a gap between the stockers, and the like on the basis of a driving force transmitted from the driving mechanism portion 510.

[0187] In Figs. 37a to 39c, reference numeral 521 indicates a rail portion, provided in the housing 100, for allowing the first stocker 501 to the fourth stocker 504 to be moved in parallel to a disk carrying passage. The rail portion 521 has projecting portions 505 and 506.

[0188] In addition, the rail portion 521 is the same as the rail portion 5019.

[0189] Reference numeral 522 indicates a stocker base which includes a guide portion 5221 for guiding the projecting portions 505 of a first rail portion to a fourth rail portion in the direction B or C, that is, in the direction of the stocker; a guide portion 5222 for guiding the projecting portions 506 of the first stocker to the fourth stocker in the direction B or C like the guide portion 5221; a guide portion 5223 for guiding a pin 5234 (which will be described later) of the third cam plate 523 in the direction D or E; and a guide portion 5224 for guiding a pin 5235 (which will be described later) of the third cam plate 523 in the direction D or E.

[0190] Reference numeral 523 indicates the third cam plate which includes a connecting portion 5231 connected to the pin 5142 of the third arm 514 shown in Fig. 36; a tilting guide portion 5232 in which the projecting portions 505 of the first rail portion to the fourth rail portion are inserted for adjustment of heights of the projecting portions 505; a tilting guide portion 5233 having a tilting portion for guiding the projecting portions 506 of the first stocker to the fourth stocker inserted in the tilting guide portion 5233; a pin 5234 slidably inserted in the guide portion 5223 of the stocker base 522; and a pin 5235 slidably inserted in the guide portion 5224 of the stocker base 522.

[0191] Reference numeral 524 indicates a stocker separating portion composed of a stocker separating portion 5241 and a stocker separating portion 5242. The stocker separating portion 5241 is contained in a containing portion 5254 (which will be described later) of a second cam plate 525 and is adapted to separate a desired stocker by movement of the second cam plate 525. Similarly, the stocker separating portion 5242 is contained in a containing portion 5255 of the second cam plate 525 and is adapted to separate a desired stocker by movement of the second cam plate 525.

[0192] Reference numeral 525 indicates the second cam plate includes a height adjusting portion 5252, part of which is formed in a comb-shape 52521, into which the projecting portions 505 of the first rail portion to the fourth rail portion are inserted for adjustment of heights of the projecting portions 505; a height adjusting portion

5253, part of which is formed in a comb-shape 52531, into which the projecting portions 506 of the first rail portion to the fourth rail portion are inserted for adjustment of heights of the projecting portions 506; the containing portion 5254 for containing the stocker separating portion 5241; and the containing portion 5255 for containing the stocker separating portion 5242.

[0193] Reference numeral 526 indicates a base portion which forms a side wall of the base portion 451. The base portion 526 includes a sliding hole 5261 in which a sliding portion 5245 of the stocker separating portion 5241 is inserted in such a manner as to be slidably moved in the direction D or E; a sliding hole 5262 in which a sliding portion 5246 of the stocker separating portion 5242 is inserted in such a manner as to be slidably moved in the direction D or E; sliding holes 5263 and 5264 in which projecting portions (not shown) formed on the operating mechanism portion 450 shown in Figs. 18a and 18b for sliding movement of the operating mechanism portion 450 in the direction D or E; a pin 5265 inserted both in a sliding hole 5272 (which will be described later) of a first cam plate 527 and a sliding hole 5281 (which will be described later) formed in a side base 528 in such a manner as to be slidably moved in the direction F or G; and a pin 5266 inserted both in a sliding hole 5273 (which will be described later) of the first cam plate 528 and a sliding hole 5282 (which will be described later) formed in the side base 528 in such a manner as to be slidably moved in the direction F or G.

[0194] Reference numeral 527 indicates the first cam plate which includes a connecting portion 5271 connected to a pin 51331 formed on the plate arm 5133 shown in Fig. 36 for moving the first cam plate 527 in the direction D or E on the basis of the motion of the plate arm 5133; a sliding hole 5272 in which the pin 5265 (which will be described later) formed on the base portion 526 is inserted in such a manner as to be slidably moved in the direction F or G; a sliding hole 5273 in which the pin 5266 (which will be described later) formed on the base portion 526 is inserted in such a manner as to be slidably moved in the direction F or G; a pin 5274 inserted in a sliding hole 5283 (which will be described later) formed in the side base 528 in such a manner as to be slidably moved in the direction D or E; and a pin 5275 inserted in a sliding hole 5284 (which will be described later) formed in the side base portion 528 in such a manner as to be slidably moved in the direction D or E.

[0195] Reference numeral 528 indicates the side base portion which forms a side wall of the housing 100. The side base portion 528 includes the sliding hole 5281 in which the pin 5265 formed on the base portion 526 is inserted in such a manner as to be slidably moved in the direction F or G; the sliding hole 5282 in which the pin 5266 formed on the base portion 526 is inserted in such a manner as to be slidably moved in the direction F or G; the sliding hole 5283 in which the pin 5274 formed on the first cam plate 527 is inserted in such a manner as

to be slidably moved in the direction D or E; and the sliding hole 5284 in which the pin 5275 formed on the first cam plate 527 is inserted in such a manner as to be slidably moved in the direction D or E.

[0196] In addition, the side base portion 528 is mounted on the housing 100.

[0197] The components described in the order of the rail portion 521 to the side base 527 are mounted from the inside to the outside of the disk system in the order of the rail portion 521, stocker base 522, third cam plate 523 including the stocker separating portion 524, second cam plate 525, base portion 526, first cam plate 527, and side base 528.

[0198] These rail portion 521, stocker base 522, third cam plate 523, stocker separating portion 524, second cam plate 525, base portion 526, first cam plate 527, and side base 528 constitute the moving mechanism portion 520.

[0199] With this moving mechanism portion 520 having the above configuration, the height of each stocker can be adjusted and also a desired stocker can be certainly separated by a plurality of the cam plates on the basis of the motion of the driving mechanism portion 510.

[0200] Next, there will be described an operational mode of the moving mechanism portion 520 on the basis of a relationship between the sliding holes formed in the first cam plate 527, second cam plate 525, and third cam plate 523, and the projecting portions formed on the rail portions, with reference to Figs. 39a to 63e.

[0201] Fig. 39a is a detail view illustrating the first cam plate 527; Fig. 39b is a detail view illustrating the second cam plate 525 provided with the stocker separating portion 524; and Fig. 39c is a detail view illustrating the third cam plate 523.

[0202] Fig. 40 is a table showing operational states of the first cam plate 527, second cam plate 525 and the third cam plate 523 on the basis of the motion of the cam portion 511 of the driving mechanism portion 510; and Fig. 41, is a table showing positions of the projecting portions of the rail portions 521 at the first cam plate 527, second cam plate 525 and the third cam plate 523, in accordance with the operations shown in Fig. 40, respectively.

[0203] Fig. 42a to Fig. 63e are views showing positional relationships between the first cam plate 527, second cam plate 525 and third cam plate 523, and the projecting portions of the rail portions shown in Fig. 41.

[0204] Each of Figs. 42a, 43a, ..., 63a shows a positional relationship between part of the driving mechanism portion 510 and positions of the respective connecting portions; each of Figs. 42b, 43b, ..., 63b shows a positional relationship between the guide portion 521 and the stocker base 522, and the projecting portions formed on the rail portions; each of Figs. 42c, 43c, ..., 63c shows a positional relationship between the second cam plate 525 provided with the stocker separating portion 524, and the projecting portions formed

on the stocker; each of Figs. 42d, 43d, ..., 63d shows a positional relationship between the base portion 526 and the first cam plate 527, and the projecting portions formed on the stocker; and each of Figs. 42f, 43f, ..., 63f shows a positional relationship between the first cam plate 527 and the side portion 528, and the projecting portions formed on the rail portions 521.

[0205] The operation of the moving mechanism portion 520 will be described with reference to Figs. 39a to 63e.

[0206] Fig. 39a shows setting positions for allowing specific operations of the disk system. As shown in this figure, eight pieces of the setting positions "1" to "8" are formed by slidable movement of the pin 5265 provided on the base portion 526 in the sliding hole 5272 of the first cam plate 527.

[0207] Fig. 39b shows a setting position at which the disk system performs a specific operation. The height setting portion 5252 of the second cam plate 525 slidably moves a setting position of the projecting portion 505 of the rail portion 521 on the basis of the motion of the cam portion 511 of the driving mechanism portion 510, to determine the setting position "a", "b", "c" or "d". The setting position "a" is set at the comb-shaped portion 52521; the setting position "d" is set at a separating hole 52411 of the stocker separating portion; and the setting position "b" or "c" is set in the height adjusting portion 5252.

[0208] Fig. 39c shows a setting position at which the disk system performs a specific operation. The tilting guide portion 5232 of the third cam plate 523 slidably moves the projecting portion 505 of the rail portion 521 on the basis of the motion of the cam portion 511 of the driving mechanism portion 510, to thereby determine either of five setting positions.

[0209] With respect to the table of Fig. 40, the process in which the projecting portion of the stocker is slidably moved from one end 51121 to the other end 51122 of the outer peripheral sliding hole 5112 formed in the driving mechanism portion 510 and the projecting portion of the stocker is slidably moved from one end 51131 to the other end 51132 of the inner peripheral sliding hole 5113, is divided into 22 steps. The table of Fig. 40 shows, for each of the 22 steps thus divided from the process, a positional relationship between the first cam plate 527, second cam plate 525 and third cam plate 523 and the projecting portion of the stocker, and an operational mode of the disk system.

[0210] Fig. 41 shows, for each of the 22 steps divided from the operational process shown in Fig. 40, a positional relationship between the first cam plate 527, second cam plate 525, and the third cam plate 523, and the projecting portion of the stocker.

[0211] Figs. 42a to 63e show the first step (hereinafter, referred to as a "NO1") to the 22th step (hereinafter, referred to as a "NO22") shown in Figs. 40 and 41, respectively. To be more specific, Figs. 42a to 42e show the step NO1 shown in Figs. 40 and 41; Figs. 63a to 63e

show the step NO22; and Figs. 43a-43e to Figs. 62a-62e show the steps NO2 to NO21, respectively.

[0212] Hereinafter, operation of the moving mechanism portion 520 will be described in order for each step with reference to Figs. 39a to 39c, and Figs. 40 and 41.

[0213] First, the step NO1 shows an operational mode for carrying a disk R1 into the first stocker 501. In third mode, as shown in Fig. 40, the first cam plate is set at a position "1", the second cam plate is set at a position "a", and the third cam plate is set at a position "A".

[0214] Accordingly, as shown in Fig. 42c, the projecting portion 505 of the rail portion 521 is meshed with a comb-like portion formed on the third cam plate 527, to thus lock the height of the stocker.

[0215] When the cam portion 511 of the driving mechanism portion 510 is rotated an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO1 is shifted to the operating state at the step NO2 in which the locking of the stocker is released.

[0216] The operating state at the step NO2 is shown in Figs. 43a to 43e, in which the first cam plate 527 is left at the position "1" and the third cam plate 523 is also left at the position "A", and the second cam plate 525 is set at a position "b".

[0217] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO2, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO2 is shifted to the operating state at the step NO3, in which the first stocker to the fourth stocker are lifted one stage from the original positions.

[0218] The operating state at the step NO3 is shown in Figs. 44a to 44e, in which the second cam plate 525 is left at the position "b", and the first cam plate 527 is set at a position "2" and the third cam plate 523 is set at a position "B".

[0219] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO3, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO3 is shifted to the operating state at the step NO4, in which the first stocker to the fourth stocker are locked and the disk R is carried into the second stocker 502.

[0220] The operating state at the step NO4 is shown in Figs. 45a to 45e, in which the first cam plate 527 is left at the position "2" and the third cam plate 523 is also left at the position "B", and the second cam plate 525 is set at the position "a".

[0221] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO4, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO4 is shifted to the operating state at the step NO5.

[0222] The operating state at the step NO5 is shown in Figs. 46a to 46e, in which the locking at the step NO4 is released, and the first cam plate 527 is left at the position "2" and the third cam plate 523 is also left at the position "B", and the second cam plate 525 is set at the

position "b".

[0223] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO5, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO5 is shifted to the operating state at the step NO6.

[0224] The operating state at the step NO6 is shown in Figs. 47a to 47e, in which the first stocker to the fourth stocker are lifted one stage from the original positions.

[0225] In this operating state, the second cam plate 525 is left at the position "b", and the first cam plate 527 is set at a position "3" and the third cam plate 523 is set at a position "C".

[0226] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO6, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO6 is shifted to the operating state at the step NO7, in which the first stocker to the fourth stocker are locked, and the disk R is carried into the third stocker 503.

[0227] The operating state at the step NO7 is shown in Figs. 48a to 48e, in which the first cam plate 527 is left at the position "3" and also the third cam plate 523 is left at the position "C", and the second cam plate 525 is set at the position "a".

[0228] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO7, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO7 is shifted to the operating state at the step NO8.

[0229] The operating state at the step NO8 is shown in Figs. 49a to 49e, in which the locking at the step NO7 is released, and the first cam plate 527 is left at the position "3" and also the third cam plate 523 is left at the position "C", and the second cam plate 525 is set at the position "b".

[0230] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO8, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO8 is shifted to the operating state at the step NO9.

[0231] The operating state at the step NO9 is shown in Figs. 50a to 50e, in which the first stocker to the fourth stocker are lifted from the original positions.

[0232] In this operating state, the second cam plate 525 is left at the position "b", and the first cam plate 527 is set at a position "4" and the third cam plate 523 is set at a position "D".

[0233] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO9, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO9 is shifted to the operating state at the step NO10, in which the first stocker to the fourth stocker are locked and the disk R is carried into the fourth stocker 504.

[0234] The operating state at the step NO10 is shown in Figs. 51a to 51e, in which the first cam plate 527 is left at the position "4" and also the third cam plate 523 is left

at the position "D", and the second cam plate 525 is set at the position "a".

[0235] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO10, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO10 is shifted to the operating state at the step NO11.

[0236] The operating state at the step NO11 is shown in Figs. 52a to 52e, in which the locking at the step NO10 is released, and the first cam plate 527 is left at the position "4" and also the third cam plate 523 is left at the position "D", and the second cam plate 525 is set at the position "b".

[0237] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO11, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO11 is shifted to the operating state at the step NO12.

[0238] The operating state at the step NO12 is shown in Figs. 53a to 53e, in which the first cam plate 527 is set at a position "5", the second cam plate 525 is set at a position "c", and the third cam plate 523 is set at a position "E". In this operating state, the fourth stocker 504 is set at a standby position for separating the fourth stocker 504 from the other stockers 501 to 503.

[0239] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO12, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO12 is shifted to the operating state at the step NO13, in which the fourth stocker is separated from the first stocker to the third stocker for reproducing the disk R contained in the fourth stocker.

[0240] The operating state at the step NO13 is shown in Figs. 54a to 54e, in which the first cam plate 527 is left at the position "5" and also the third cam plate 523 is left at the position "E", and the second cam plate 525 is set at a position "d".

[0241] Here, as shown in Fig. 54b, to separate a stocker, each of both gaps between the stocker to be separated and the other stockers is tilted at a specific angle θ .

[0242] In addition, tilting angles of both gaps between the stocker to be separated and the other stockers may be identical to or different from each other irrespective of the position of the stocker to be separated. For example, when the second stocker is separated from the other stockers, a tilting angle of a gap between the first stocker 501 and the second stocker 502 may be identical to or different from a tilting angle of a gap between the second stocker 502 and the third and fourth stockers 503 and 504.

[0243] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO13, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO13 is shifted to the operating state at the step NO14.

[0244] The operating state at the step NO14 is shown

in Figs. 55a to 55e, in which the first cam plate 527 is left at the position "5" and also the third cam plate 523 is left at the position "E", and the second cam plate 525 is set at the position "c". In this operating state, the gaps between the projecting portions of the stockers become narrow again.

[0245] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO14, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO14 is shifted to the operating state at the step NO15.

[0246] The operating state at the step NO15 is shown in Figs. 56a to 56e, in which the second cam plate 525 is left at the position "c" and also the third cam plate 523 is left at the position "E", and the first cam plate 527 is set at a position "6". In this operating state, the base portion 526 is lifted.

[0247] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO15, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO15 is shifted to the operating state at the step NO16; in which the first, second and fourth stockers are separated from the third stocker for reproducing the disk R contained in the third stocker.

[0248] The operating state at the step NO16 is shown in Figs. 57a to 57e, in which the first cam plate 527 is left at the position "6" and also the third cam plate 523 is left at the position "E", and the second cam plate 525 is set at a position "d".

[0249] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO16, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO16 is shifted to the operating state at the step NO17.

[0250] The operating state at the step NO17 is shown in Figs. 58a to 58e, in which the first cam plate 527 is left at the position "6" and also the third cam plate 523 is left at the position "E", and the second cam plate 525 is set at the position "c".

[0251] In the operating state thus set, the gaps between the projecting portions of the first stocker 501 to the fourth stocker 504 become narrow again.

[0252] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO17, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO17 is shifted to the operating state at the step NO18.

[0253] The operating state at the step NO18 is shown in Figs. 59a to 59e, in which the second cam plate 525 is left at the position "c" and also the third cam plate 523 is left at the position "E", and the first cam plate 527 is set at a position "7". In this operating state, the base portion 526 is lifted.

[0254] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO18, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step

NO18 is shifted to the operating state at the step NO19, in which the first, third and fourth stockers are separated from the second stocker for reproducing the disk R contained in the second stocker.

[0255] The operating state at the step NO19 is shown in Figs. 60a to 60e, in which the first cam plate 527 is left at the position "7" and also the third cam plate 523 is left at the position "E", and the second cam plate 525 is set at the position "d".

[0256] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO19, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO19 is shifted to the operating state at the step NO20.

[0257] The operating state at the step NO20 is shown in Figs. 61a to 61e, in which the first cam plate 527 is left at the position "7" and also the third cam plate 523 is left at the position "E", and the second cam plate 525 is set at the position "c".

[0258] In the operating thus set, the gaps between the projecting portions of the first stocker 501 to the fourth stocker 504 become narrow again.

[0259] When the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO20, an angle corresponding to one step in the direction B in Fig. 36, the operating state at the step NO20 is shifted to the operating state at the step NO21.

[0260] The operating state at the step NO21 is shown in Figs. 62a to 62e, in which the second cam plate 525 is left at the position "c" and also the third cam plate is left at the position "E", and the first cam plate 527 is set at a position "8". In this operating state, the base portion 526 is lifted.

[0261] Finally, when the cam portion 511 of the driving mechanism portion 510 is rotated, from the operating state at the step NO21, an angle corresponding to one step in the direction B in Fig. 36, that is, the pin 5124 of the first arm 512 shown in Fig. 36 is set at the other end 51122 of the outer peripheral sliding hole 5112 of the cam portion 511 and the pin 51321 of the cam arm 5132 is set at the other end 51132 of the inner peripheral sliding hole 5113 of the cam portion 511, the operating state at the step NO21 is shifted to the operating state at the step NO22.

[0262] The operating state at the step NO22 is shown in Figs. 63a to 63e, in which the first cam plate 527 is left at the position "8" and also the third cam plate 523 is left at the position "E", and the second cam plate 525 is set at the position "d".

[0263] After completion of the operating step NO22, the next operating process is performed in the direction reversed to that described above, that is, in the order of the steps NO22 → NO21 → NO20 ... → NO1.

[0264] Figs. 64a and 64b show the first cam plate 527; Figs. 65a to 65d show the second cam plate 525; and Figs. 66a to 66c show the third cam plate 523. To be more specific, Fig. 64a shows a state in which the projecting portion of the rail portion 521 is set at the posi-

tion "7" shown in Fig. 39a, and Fig. 64b shows a state in which the projecting portion of the rail portion 521 is set at the position "1" shown in Fig. 39a.

[0265] Fig. 65a shows a state in which the projecting portion of the rail portion 521 is set at the position "d" shown in Fig. 39b; Fig. 65b shows a state in which the projecting portion of the rail portion 521 is set at the position "c" shown in Fig. 39b; Fig. 65c shows a state in which the projecting portion of the rail portion 521 is set at the position "b" shown in Fig. 39b; and Fig. 65d shows a state in which the projecting portion of the rail portion 521 is set at the position "a" shown in Fig. 39b.

[0266] Fig. 66a shows a state in which the projecting portion of the rail portion 521 is set at the position "E" shown in Fig. 39c; Fig. 66b shows a state in which the projecting portion of the rail portion 521 is set at the position C shown in Fig. 39c; and Fig. 66c shows a state in which the projecting portion of the rail portion 521 is set at the position "A" shown in Fig. 39c.

[0267] With the moving mechanism portion 520 having the above configuration, operation of each stocker can be certainly controlled by controlling a rotational angle of the cam portion 511 of the driving mechanism portion 510.

[0268] In accordance with operation of the stockers described above, each stocker is set at a desired setting position by way of the sequential operating steps. For example, to obtain the step NO10 from the step NO19, the step NO19 is shifted to the step NO10 in the order of NO19 → NO18 → NO17 → ... → NO10.

[5. Description of operation of Entire Disk System]

[0269] Hereinafter, there will be described three basic operations of the entire disk system shown in the Embodiment 1 described above with reference to Fig. 67a to 95b. The three basic operations are: (1) an operation in which disks are contained in all stockers from a disk non-containing state and a specific disk is reproduced; (2) an operation in which during reproducing of a specific disk, such reproducing is switched into reproducing of another disk; and (3) an operation in which reproducing of a specific disk is stopped and the specific disk is ejected.

[0270] Referring first to Figs. 67a to 82b, there will be described the operation (1), that is, the operational step of the entire disk system from a state in which disks are contained in the first stocker 501 to the fourth stocker 504 in this order from the state with no disks contained in the disk system to a state in which a disk R2 contained in the second stocker is reproduced.

[0271] Figs. 67a and 67b are views showing a state in which no disk is contained in the disk system; Figs. 68a and 68b are views showing a state in which a command allowing a disk R1 to be inserted into the first stocker 501 is supplied from the operating portion (not shown) or the like and the first stocker is moved toward the insertion port; Figs. 69a and 69b are views showing a

state in which the disk R1 is inserted from the insertion port 101; Figs. 70a and 70b are views showing a state in which the disk R1 is contained in the disk containing portion of the first stocker 501; and Figs. 71a and 71b are views showing a state in which the first stocker 501 containing the disk R1 is moved to the original position, that is, the position shown in Figs. 67a and 67b.

[0272] Figs. 72a and 72b are views showing a state in which the stockers are entirely lifted a height corresponding to one stocker stage; Figs. 73a and 73b are views showing a state in which a command allowing a disk R2 to be inserted into the second stocker 502 is supplied from the operating portion (not shown) or the like and the second stocker is moved toward the insertion port; Figs. 74a and 74b are views showing a state in which the disk R2 is inserted from the insertion port 101; Figs. 75a and 75b are views showing a state in which the disk R2 is contained in the disk containing portion of the first stocker 502; and Figs. 76a and 76b are views showing a state in which the second stocker 502 containing the disk R2 is moved to the original position, that is, the position shown in Figs. 67a and 67b.

[0273] Figs. 77a and 77b are views showing a state in which a disk R3 is contained in the third stocker 503 and the third stocker 503 is returned to the original position, that is, the position shown in Figs. 67a and 67b; and Figs. 78a and 78b are views showing a state in which a disk R4 is contained in the fourth stocker 504 and the fourth stocker 504 is returned to the original position, that is, the position shown in Figs. 67a and 67b.

[0274] Figs. 79a and 79b are views showing a state in which a command allowing reproducing of the disk R2 is supplied from the operating portion (not shown) and the second stocker 502 containing the disk R2 is separated from the other stockers, that is, the first stocker 501, third stocker 503 and fourth stocker 504; and Figs. 80a and 80b are views showing a state in which the disk clasper portion 300 and the disk reproducing portion 400 are moved for reproducing the disk R2.

[0275] Figs. 81a and 81b are views showing a state in which the second stocker 502 is moved toward the insertion port; and Figs. 82a and 82b are views showing a state in which the disk R2 is held between the disk clasper portion 300 and the disk reproducing portion 400 and the second stocker 502 is returned to the original position, followed by reproducing of the disk R2.

[0276] In addition, each of Figs. 67a, ..., 82a is a sectional top view, and each of Figs. 67b, ..., 82b is a sectional side view taken on line a-a.

[0277] First, as shown in Fig. 67, in the state in which no disk is contained in the disk system, that is, in the initial state, the first stocker 501 to the fourth stocker 504 are disposed closely to a peripheral edge portion of the housing 100 on the opposed side of the insertion port 101 and further upper and lower gaps are little provided between the stockers.

[0278] Further, the disk reproducing portion 400 and the disk clasper portion 300 are disposed closely to the

upper disk roller 201 and the lower disk roller 202 disposed near the insertion port 101, and the disk system is ready for reception of a command allowing insertion of a disk from the operating portion (not shown) in a state in which a gap between both the disk rollers is kept at minimum.

[0279] Then, a specific command allowing the disk R1 to be contained in the first stocker 501 is supplied from the operating portion.

[0280] Next, the first stocker 501 is moved, by the above-described moving mechanism portion 520 for moving each stocker, from the position shown in Figs. 67a and 67b in the direction B and is set at a specific position shown in Figs. 68a and 68b, that is, a position at which the stocker 501 can contain the disk R₁; and the first stocker 501 is ready for insertion of the disk.

[0281] When the disk R₁ is inserted from the insertion port 101 as shown in Figs. 69a and 69b, it is contained in the first stocker 501 by the disk loading mechanism 200 (Figs. 70a and 70b), and the first stocker 501 is moved in the direction A to be returned to the original position shown in Figs. 67a and 67b (see Figs. 71a and 71b).

[0282] Before insertion of the next disk R₂, to adjust a height of the stocker 502 for containing the disk R₂ to a height of the insertion port 101, the stockers are entirely lifted a height corresponding to one stocker stage by the above moving mechanism portion 520 (Figs. 72a and 72b), and then the stocker 502 for containing the disk R₂ is moved in the direction B and is set at a specific position (Figs. 73a and 73b). And, the disk R₂ inserted from the insertion port 101 is carried in the disk system by the disk loading portion 200 (Figs. 74a and 74b) and is contained and held in the second stocker 502 (Figs. 75a and 75b). As shown in Figs. 76a and 76b, the second stocker 502 is moved in the direction A to be returned to the original position.

[0283] Similarly, as shown in Figs. 78a and 78b, the disk R₃ is contained in the third stocker 503, and as shown in Figs. 79a and 79b, the disk R₄ is contained in the fourth stocker 504.

[0284] In this case, as shown in Fig. 79b, the stockers are separated from each other. To be more specific, the second stocker 502 is separated from the first, second, and third stockers 501, 503 and 504 in such a manner that the gap between the first stocker 501 and the second stocker 502 is tilted at a first angle θ_1 and the gap between the second stocker 502 and the third and fourth stockers 503 and 504 is tilted at a second angle θ_2 .

[0285] Next, when a command allowing reproducing of the disk R₂ is supplied from the operating portion (not shown); as shown in Figs. 79a and 79b, the above moving mechanism portion 520 sets the second stocker 502 containing the target disk R₂ at a specific height at which the disk R₂ can be reproduced, and tilts the other stockers for separating the second stocker 502 therefrom.

[0286] Then, the disk clasper portion 300 is inserted in the gap between the disks R₁ and R₂, and the disk reproducing portion 400 is moved in the direction A and is inserted in the gap between the disks R₂ and R₃, with the gap between the upper disk roller 201 and the lower disk roller 202 being enlarged (Figs. 80a and 80b).

[0287] Further, to reproduce the disk R₂ as shown Figs. 81a and 81b, the second stocker 502 containing the disk R₂ is moved in the direction B up to a specific position.

[0288] Next, as shown in Figs. 82a and 82b, the disk clasper portion 300 is further moved in the direction A to be inserted in the gap between the first stocker 501 and the second stocker 502. Similarly, the disk reproducing portion 400 is further moved in the direction A to be inserted in the gap between the second stocker 502 and the third stocker 502. At this time, the gap between the upper disk roller 201 and the lower disk roller 202 is enlarged at maximum. Thus, the disk R₂ is held between the disk clasper portion 300 and the disk reproducing portion 400, and then the second stocker 502 is moved to the original position and releases the holding of the disk R₂, followed by reproducing of the disk R₂.

[0289] Next, there will be described the operation (2), that is, the operational step of the entire disk system in which reproducing of the disk R₂ is stopped and the disk R₂ is contained in the second stocker 502 again, and the disk R₃ contained in the third stocker 503 is reproduced, with reference to Figs. 83a to 90b.

[0290] Figs. 83a and 83b are views showing a state in which the disk R₃ is contained in the third stocker 503 and the disk R₂ is reproduced; Figs. 84a and 84b are views showing a state in which the second stocker 502 is moved to a position at which the second stocker 502 can contain the disk R₂ while holding the disk R₂ and the disk reproducing portion 400 is slightly returned to the original position as shown in Figs. 67a and 67b; Figs. 85a and 85b are views showing a state in which the second stocker 502 contains the disk R₂ and is returned to the original position; and Figs. 86a and 86b are views showing a state in which movement of the disk clasper portion 300 and the disk reproducing portion 400 to the original positions is completed.

[0291] Figs. 87a and 87b are views showing a state in which the stockers are lifted while being separated from each other; Figs. 88a and 88b are views showing a state in which the disk clasper portion 300 and the disk reproducing portion 400 are moved on the third stocker 503 side; Figs. 89a and 89b are views showing a state in which the third stocker 503 is moved on the insertion port 101 side; and Figs. 90a and 90b are views showing a state in which the disk R₃ is held between the disk clasper portion 300 and the disk reproducing portion 400, and the third stocker 503 is moved to the original position and releases the holding of the disk R₃, followed by reproducing of the disk R₃.

[0292] In addition, each of Figs. 83a, ..., 90a is a sec-

tional top view, and each of Figs. 83b, ..., 90b is a sectional side view taken on line a-a.

[0293] First, when a command allowing reproducing of the disk R3 is supplied from the operating portion (not shown) in the state in which the disk R2 is held between the disk clamber portion 300 and the disk reproducing portion 400 as shown in Figs. 83a and 83b for reproducing the disk R2, the second stocker 502 is first moved in the direction B to hold and contain the disk R2 located at the reproducing position.

[0294] Next, the disk reproducing portion 400 releases the disk R2 and is slightly returned in the direction A (Figs. 84a and 84b).

[0295] The second stocker 502, which contains the disk R2 with its holding by the disk clamber portion 300 and the disk reproducing portion 400 being released, is moved in the direction A to be returned to the original position (Figs. 85a and 85b), and as shown in Figs. 86a and 86b, not only the disk reproducing portion 400 but also the disk clamber portion 300 is returned to the original position, and the gap between the upper disk roller 201 and the lower disk roller 202 is reduced at minimum.

[0296] Next, to adjust the height of the third stocker 503 to the height of the insertion port 101, the second stocker 502 and the fourth stocker 503 are lifted while being separated from each other (Figs. 87a and 87b), and the disk clamber portion 300 and the disk reproducing portion 400 are moved in the direction A and also the gap between the upper disk roller 201 and the lower disk roller 202 is enlarged. Then, the disk clamber portion 300 is inserted in the gap between the disks R2 and R3, and the disk reproducing portion 400 is disposed substantially under the disk R3 (Figs. 88a and 88b).

[0297] Further, the third stocker 503 containing the disk R3 is moved in the direction B up to a position at which the disk R3 can be reproduced (Figs. 89a and 89b), and as shown in Figs. 90a and 90b, the disk reproducing portion 400 is further moved in the direction A so that the disk R3 is held between the disk clamber portion 300 and the disk reproducing portion 400.

[0298] After holding the disk R3, the gap between the upper disk roller 201 and the lower disk roller 202 is enlarged at maximum, and the third stocker 503 is moved in the direction A to be returned to the original position and releases the holding of the disk R3, to start reproducing of the disk R3.

[0299] Finally, there will be described the operation (3), that is, the operating in which the disk R2 is ejected during reproducing of the disk R3, with reference to Figs. 90a to 96b.

[0300] Figs. 91a and 91b are views showing a state being in the course of returning the disk reproducing portion 400 to the original position from the state shown in Figs. 90a and 90b; Figs. 92a and 92b are views showing a state in which the third stocker 503 and the disk R3 are returned to the original positions; Figs. 93a and 93b are views showing a state in which movement of the

disk clamber portion 300 and the disk reproducing portion 400 to the original positions is completed; Figs. 94a and 94b are views showing a state in which the stockers are entirely lowered; Figs. 95a and 95b are views showing a state in which the second stocker 502 is moved on the insertion port 101 side and the disk R2 is held by the disk loading mechanism 200; and Figs. 96a and 96b are views showing a state in which the disk R2 is ejected.

[0301] In addition, each of Fig. 90a, ..., 96a is a sectional top view, and each of Figs. 90b, ..., 96b is a sectional side view taken on line a-a.

[0302] First, when a command allowing ejection of the disk R2 is supplied from the operating portion (not shown) in the state in which the disk R3 is held between the disk clamber portion 300 and the disk reproducing portion 400 as shown in Figs. 90a and 90b, the third stocker 503 is moved to a position at which it can contain the disk R3, and holds and contains the disk R3.

[0303] Then, the disk clamber portion 300 and the disk reproducing portion 400 are moved in the direction B and the gap between the upper disk roller 201 and the lower disk roller 202 is enlarged (Figs. 91a and 91b).

[0304] After the operating state shown in Figs. 91a and 91b, as shown in Figs. 92a and 92b, the third stocker 503 is moved in the direction A in the state in which it contains the disk R3, to be returned to the original position.

[0305] Next, as shown in Figs. 93a and 93b, the disk clamber portion 300 is further moved in the direction B to be returned to the original position and the gap between the upper disk roller 201 and the lower disk roller 202 is reduced at minimum. Also, to adjust the height of the second stocker 502 to the height of the insertion port 101, the entire stockers are brought in close-contact with each other and are moved (Figs. 94a and 94b).

[0306] Thus, as shown in Figs. 96a and 96b, the second stocker 502 containing the disk R2 is moved in the direction B, and the disk R2 is ejected by the disk loading portion 200.

[0307] According to the disk system configured as described above, spaces in which a base plate of the driving mechanism portion 510 of the disk containing mechanism 500 and the like can be provided can be ensured in the housing at both a portion over the first stocker and a portion under the fourth stocker, it is possible to eliminate an unnecessary space and minimize the length of the disk carrying path as seen from top, and hence to miniaturize the disk system.

[0308] Further, it is possible to freely insert or eject disks one by one, and hence to improve usability of an operator.

[0309] Since the upper disk roller and the lower disk roller can be moved downward and upward respectively, a disk space necessary for reproducing a disk can be ensured in a gap between the upper disk roller and the lower disk roller. This makes it possible to reduce a space due to the disk space, and hence to miniaturize

the disk system.

[0310] While the first embodiment has been described regarding reproducing of disks, the operational mode of disks to which the present invention is applicable is not limited thereto. For example, the same effect can be obtained even when the present invention is applied to other operational modes of disks such as recording of disks, and erasing of disks for erasing information recorded in disks.

Embodiment 2

[0311] Next, a disk system according to a second embodiment of the present invention will be described with reference to Figs. 97a to 102b.

[0312] Although in Embodiment 1 the disk loading mechanism 200 is so configured as shown in Fig. 6a to 9d, it may be so configured as shown in Figs. 97a to 102b with the same effect.

[0313] Figs. 97a to 99b show an essential portion of a disk carrying mechanism 200 on an upper disk roller 201 side; wherein Figs. 97a and 97b are front views of the essential portion; Figs. 98a and 98b are top views of the essential portion; and Figs. 99a and 99b are sectional side views of the essential portion. In addition, each of Figs. 97a, 98a and 99a shows a state in which a disk R is held, and each of Figs. 97b, 98b and 99b shows a state in which the disk R is released.

[0314] Figs. 100a to 102b show an essential portion of the disk carrying mechanism 200 on a lower disk roller 202 side, wherein Figs. 100a and 100b are front views of the essential portion; Figs. 101a and 101b are top views of the essential portion; and Figs. 102a and 102b are sectional side views of the essential portion. In addition, each of Figs. 100a, 101a and 102a shows a state in which a disk R is held, and each of Figs. 100b, 101b and 102b shows a state in which the disk R is released.

[0315] First, a configuration and an operation of the upper disk roller portion will be described.

[0316] In Figs. 97a to 99b, reference numeral 601 indicates an upper roller arm having one end for supporting the upper disk roller 201 and also having at a portion a pin 6011; 602 is an end portion of a slider 304 having at a portion a pin 6021; and 603 is an open link having at one end a contact portion 6031 which is brought in contact with the pin 6021 formed at the end portion 602 of the slider 304.

[0317] As shown in Figs. 99a and 99b, projecting portions 6022 to 6024 are formed on a side surface of the end portion 602 of the slider 304.

[0318] Reference numeral 604 indicates a roller open cam plate having in a portion a sliding hole 6041 in which the pin 6011 formed on the upper roller arm 601 is slidably moved; and 605 is a spring having one end 6051 engaged with a portion 102 of a housing 100 and the other end 6052 engaged with the roller open cam plate 604, wherein the one end 6051 and the other end

6052 are compressed to each other.

[0319] The operation of the upper disk roller will be described below.

[0320] First, in the case other than reproducing the disk R, that is, in the case where the disk R is held between the upper disk roller 201 and the lower disk roller 202, the end portion 602 of the slider 304 presses the roller open cam plate 604 by the pin 6021 in the direction B shown in Figs. 98a and 98b.

[0321] Accordingly, the spring 605 is elongated longer than a usual length, and the open link 603 is in contact with the pin 6021 by a biasing force of the spring 605 exerted in the direction where the spring 605 is returned to the original length.

[0322] Next, in the case of reproducing the disk R, since the slider 304 is moved in the direction A shown in Figs. 98a and 98b, the end portion 602 of the slider 304 is also moved in the direction A.

[0323] As a result, the open link 603 locked in contact with the pin 6021 formed on the end portion 602 is made rotatable in the direction C, so that the roller open cam plate 604, which is connected and locked to the open link 603 and is biased by the spring 605 in the direction B, can be pulled in the direction B.

[0324] By pulling of the roller open cam plate 604 in the direction B, the pin 6011 formed on the upper roller arm 601 is slid in the sliding hole 6041 formed in the roller open cam plate 604 up to a position shown in Fig. 99b, and is thus lifted a height "d", and correspondingly, the upper disk roller 201 is lifted approximately the height "d".

[0325] Further, a configuration and an operation of the lower disk roller will be described.

[0326] In Fig. 100a to 102b, reference numeral 611 indicates a lower roller arm having at a portion a contact portion 6111 with which part of the projecting portions 6022 to 6024 formed on the end portion 602 of the slider 304 are brought in contact.

[0327] Next, the operation of the lower disk roller will be described.

[0328] First, in the case other than reproducing of the disk R, that is, in the case where the disk R is held between the upper disk roller 201 and the lower disk roller 202, since the slider 304 is moved in the direction D, the contact portion 6111 of the lower roller arm 611 is not brought in contact with the projecting portions 6022 to 6024 formed on the end portion 602 of the slider 304 and the lower roller arm 611 is biased in the direction F by a biasing force of a biasing portion (not shown) for usually biasing it in the direction F.

[0329] Next, in the case of reproducing the disk R, since the slider 304 is moved in the direction E shown in Fig. 102a and 102b, the end portion 602 of the slider 304 is also moved in the direction E.

[0330] Accordingly, the projecting portions 6022 to 6024 formed on the end portion 602 of the slider 304 are brought in contact with the contact portion 6111 of the lower roller arm 611, so that the contact portion

6111 is turned in the direction H around a turning shaft 6112.

[0331] Accordingly, the lower disk roller connected to the lower roller arm is moved in the direction G.

[0332] With this configuration, the disk roller portion can be accurately operated with a simple structure, so that it is possible to further improve the reliability of the disk system.

[0333] In the disk roller portion 200 in Embodiment 2, the upper disk roller is shown in Fig. 97a to 99b and the lower disk roller is shown in Fig. 100a to 102b. Figs. 103 to 105b show arrangements in which the combination of the upper disk roller 201 and the lower disk roller 202 is disposed on each of the right and left sides.

[0334] Figs. 103a and 103b are front views of an essential portion of the combination of the upper and lower disk rollers, wherein Fig. 103a shows a right side portion as seen from the insertion port, and Fig. 103b shows a left side portion as seen from the insertion port.

[0335] Figs. 104a and 104b are top views of the essential portion, wherein Fig. 104a shows the left side portion as seen from the insertion port, and Fig. 104b shows the right side portion as seen from the insertion port.

[0336] Figs. 105a and 105b are sectional side views of the essential portion, wherein Fig. 105a shows the left side portion as seen from the insertion port, and Fig. 105b shows the right side portion as seen from the insertion port, like Figs. 104a and 104b.

Embodiment 3

[0337] Next, a disk system according to a third embodiment of the present invention will be described.

[0338] Although in Embodiment 2 the upper disk roller is so configured as shown in Figs. 97a to 99b and the lower disk roller is so configured as shown in Figs. 100a to 102b, the upper and lower disk rollers may be reversely configured, that is, the lower disk roller may be so configured as shown in Figs. 97a to 99b and the upper disk roller may be so configured as shown in Figs. 100a to 102b, with the same effect.

Embodiment 4

[0339] Next, a disk system according to a fourth embodiment of the present invention will be described.

[0340] The disk loading mechanism 200 in Embodiment 1 may be disposed on either of the right and left sides and the disk loading mechanism 200 in Embodiment 2 may be disposed on the other side. Even in this embodiment, an effect similar to that in each of Embodiments 1 and 2 can be obtained.

Embodiment 5

[0341] Next, a disk system according to a fifth embodiment of the present invention will be described.

[0342] Although having been not described in Embodiment 1, the first and second roller moving means, that is, the roller open cam plate 203, upper roller arm 204, lower roller arm 205, and slider 304 may be moved in such a manner that the first and second disk rollers, that is, the upper disk roller 201 and the lower disk roller 202 are opposed to each other. Even in this embodiment, an effect similar to that in Embodiment 1 can be obtained.

Embodiment 6

[0343] Next, a disk system according to a sixth embodiment of the present invention will be described.

[0344] Although having been not described in Embodiment 1, when the operational state of the disk driving means, that is, the disk reproducing portion 400 is switched into the non-operational state, the first and second roller moving means, that is, the roller open cam plate 203, upper roller arm 204, lower roller arm 205, and slider 304 move the first and second disk rollers, that is, the upper disk roller 201 and the lower disk roller 202 at positions set before the disk driving means, that is, the disk reproducing portion 400 is operated. Even in this embodiment, an effect similar to that in Embodiment 1 can be obtained.

Embodiment 7

[0345] Next, a disk system according to a seventh embodiment of the present invention will be described.

[0346] Although having been not described in Embodiment 1, when the disk (R) inserted in the disk system is ejected from the system, the first and second roller moving means, that is, the roller open cam plate 203, upper roller arm 204, lower roller arm 205, and slider 304 move the first and second disk rollers, that is, the upper disk roller 201 and lower disk roller 202 in such a manner that the upper disk roller 201 is brought in contact with either of both surfaces of the disk (R) and the lower disk roller 202 is brought in contact with the other of both the surfaces of the disk (R) for holding the disk (R) between the upper disk roller 201 and the lower disk roller 202.

Industrial Applicability

[0347] As described above, the disk system according to the present invention can prevent a disk from being damaged by holding the disk upon insertion or ejection of the disk and moving both roller portions holding the disk upon reproducing or exchange of the disk.

Claims

1. A disk system comprising:

first and second disk rollers (201, 202), provided opposite to each other with a disk carry-

ing path on which a disk (R) is carried put therebetween, for carrying the disk (R) within the disk carrying path while holding both surfaces of the disk (R);

a disk driving means (400) for driving the disk (R);

a first roller moving means (203, 204, 304) for moving, upon operation of said disk driving means (400), said first disk roller (201) in the direction substantially perpendicular to a plane of the disk (R) opposed to said first disk roller (201) for providing a gap (d2, d3, d4) between said first disk roller (201) and the plane of said disk (R); and

a second roller moving means (203, 205, 304) for moving, upon operation of said disk driving means (400), said second disk roller (202) in the direction substantially perpendicular to the plane of the disk (R) opposed to said second disk roller (202) for providing a gap (d2, d3, d4) between said second disk roller (202) and the plane of said disk (R).

2. A disk system according to claim 1, wherein said first and second roller moving means (203, 204, 205, 304) move said first and second disk rollers (201, 202) in such a manner that said first and second disk rollers (201, 202) are opposed to each other.
3. A disk system according to claim 1, wherein when an operational state of said disk driving means (400) is switched into a non-operational state, said first and second roller moving means (203, 204, 205, 304) move said first and second disk rollers (201, 202) at positions set before operation of said disk driving means (400).
4. A disk system according to claim 1, wherein when the disk (R) inserted in said disk system is ejected out of said disk system, said first and second roller moving means (203, 204, 205, 304) move said first and second disk rollers (201, 202) in such a manner that said first disk roller (201) is brought in contact with either of both surfaces of the disk (R) and said second disk roller (202) is brought in contact with the other of both the surfaces of the disk (R) for holding the disk (R) between said first and second disk rollers (201, 202).

A. CLASSIFICATION OF SUBJECT MATTER Int.Cl ⁶ G11B17/26, G11B17/04		
According to International Patent Classification (IPC) or to both national classification and IPC		
B. FIELDS SEARCHED Minimum documentation searched (classification system followed by classification symbols) Int.Cl ⁶ G11B17/22, G11B17/04		
Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched Jitsuyo Shinan Koho 1922-1996 Toroku Jitsuyo Shinan Koho 1994-1998 Kokai Jitsuyo Shinan Koho 1971-1998 Jitsuyo Shinan Toroku Koho 1996-1998		
Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)		
C. DOCUMENTS CONSIDERED TO BE RELEVANT		
Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	JP, 5-342741, A (Clarion Co., Ltd.), December 24, 1993 (24. 12. 93) (Family: none)	1-4
<input type="checkbox"/> Further documents are listed in the continuation of Box C. <input type="checkbox"/> See patent family annex.		
Special categories of cited documents: "A" document defining the general state of the art which is not considered to be of particular relevance "E" earlier document but published on or after the international filing date "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified) "O" document referring to an oral disclosure, use, exhibition or other means "P" document published prior to the international filing date but later than the priority date claimed "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art "&" document member of the same patent family		
Date of the actual completion of the international search May 22, 1998 (22. 05. 98)		Date of mailing of the international search report June 2, 1998 (02. 06. 98)
Name and mailing address of the ISA/ Japanese Patent Office		Authorized officer
Facsimile No.		Telephone No.
